## Module 07: Efficiency

#### **Topics:**

- Basic introduction to run-time efficiency
- Analyzing recursive code
- Analyzing iterative code

# Consider the following two ways to calculate the maximum of a nonempty list. Why is one so much slower than the other?

```
def list_max(values):
    max so far = values[0]
    for v in values:
        if v > max so far:
            \max so far = v
    return max so far
def list max1(x):
    if len(x) == 1:
        return x[0]
    elif x[0] > list max1(x[1:]):
        return x[0]
    else:
        return list max1(x[1:])
```

### Comparing Algorithms

Suppose you have two algorithms to solve a problem. How can we determine which one is better?

Which is easier to understand? Implement?
 Accurate? More robust? Adaptable? Efficient?

We will use efficiency to compare algorithms.

## Efficiency

The most common measure of efficiency is *time efficiency*, or how long it takes an algorithm to solve a problem.

Depends on its implementation

Another measure of efficiency is *space efficiency*, or how much space (memory) an algorithm requires to solve a problem.

## Efficiency: measurement of Running Time of an algorithm

What is our unit of measurement? Seconds?

- Dependent on when statement made, what computer, how much RAM, what language used, what OS, etc.
- Do we consider the average time over all possible problems? Just one? Which one?

The actual time taken is not a great choice. Instead, we will count number of steps or basic operations performed.

#### Example

What is the number of operations executed when calling this function?

```
def sum all(values):
   sum = 0
   ind = 0
   upper = len(values)
   while (ind < upper):</pre>
      sum = sum + values[ind]
      ind = ind + 1
   return sum
```

## Input size

- Let n refer to the size of the problem
  - Length of list
  - Number of characters in a string
  - Number of digits in a Nat
  - Meaning should be specified if not clear
- Running time is always stated as a function of n. We denote it by T(n)

## Running time depends on data values, not just input size

- Assume n = len(L)
- How many steps are taken by the following code?

```
ind = 0
length = len(L)
while (ind < length) and (L[ind] > 0):
    ind = ind + 1
```

## Terminology

- We will be pessimistic, and determine the largest value of T(n) possible for a fixed n
  - Worst case running time
  - This is our default meaning of "run time"
- Sometimes we are interested in the **best case**, i.e. the minimum value of T(n) possible for a fixed value of n

### Big O notation

- In practice, we are not concerned with the difference between the running times 6n + 6 and 174n + 32.
- We are interested in the *order* of a running time.
   The order is the *dominant* term without its coefficient.
- The dominant term in both 6n + 6 and 174n + 32 is n, so both are "Order n", denoted O(n)
- This is called the asymptotic run time

## Big O Examples

- 2016 = O(1)
- $12 \log n + 45 = O(\log n)$
- $12 \log n + 45n = O(n)$
- $20 n \log n + 3n + 27 = O(n \log n)$
- $3 + n + n^2 + 2^n = O(2^n)$

### Important Big O information

- In this course, we will encounter only a few orders (arranged from smallest to largest):  $O(1) < O(\log n) < O(n) < O(n\log n) < O(n^2) < O(2^n)$
- Note that these relationships hold as  $n \to \infty$
- When comparing algorithms, the most efficient algorithm is the one with the lowest order.
- If two algorithms have the same order, they are considered equivalent, but may not take exactly the same number of steps.

What is the running time of this code?

```
def list_max(values):
    max_so_far = values[0]
    for v in values:
        if v > max_so_far:
            max_so_far = v
    return max_so_far
```

## Big O arithmetic

 When adding two orders, the result is the larger of the two orders.

$$-O(\log n) + O(n) = O(n)$$

$$-0(1) + 0(1) = 0(1)$$

- How can we use this result?
  - Break code into blocks that run one after the other
  - If you determine the asymptotic run times of the blocks independently, then just add them to get the overall run time.

## Algorithm analysis

- An important skill in Computer Science is the ability to analyze a program and determine the order of its running time.
- In this course, you will not need to count operations exactly.
- Our goal is to give you experience and to work towards building your intuition.

```
sum=0
for x in lst:
    sum = sum + x
```

Each item in the list is retrieved once, so running time is O(n)

### **Basic Operations in Python**

We will make the following assumptions

Numerical operations:

```
-+,-,*,/,= are O(1)
-\max(a,b), \min(a,b) are O(1)
```

- String operations, where n = len(s)
  - $-\operatorname{len}(s)$ , s[k] are O(1)
  - -s + t is O(n + len(t))
  - Most string methods (e.g. count, find, lower) are O(n)
- print and input are dependent on the length of what is being printed and read in

#### Basic List Operations, where n = len(L)

We will make the following <u>assumptions</u>:

- len(L), L[k] are O(1)
- L + M is O(n + len(M))-L + [x] is O(n)
- sum(L), max(L), min(L) are O(n)
- L[a:b] is O(b-a), so at most O(n)-L[1:] is O(n)
- L.append(x) is O(1)

More basic list operations, where n = len(L)

We will make the following *assumptions*:

- list(range(n)) is O(n)
- Most other list methods on L (e.g. count, index, insert, pop, remove) are
   O(n)
- L.sort() is  $O(n \log n)$

CS116 Fall 2017 07: Efficiency 18

## Here are two ways to duplicate a list. Which is most efficient?

```
def duplicate1(L):
    extra = []
    for x in L:
        extra.append(x)
    return extra
def duplicate2(L):
    extra = []
    for x in L:
        extra = extra + [x]
    return extra
```

#### General Procedure for analyzing a loop

- Determine the number of iterations
- For each iteration, determine the running time of body of the loop
  - Each loop body may have the same running time,
     but that is not guaranteed
- Add together the running time of each loop body to get the overall running time

## More Big O arithmetic

 When multiplying two orders, the result is the product of the two orders.

- $-O(\log n) * O(n) = O(n \log n)$
- $-O(n) * O(n) = O(n^2)$
- How can we use this result?
  - Determine the asymptotic run time of the number of iterations of a loop
  - Determine the asymptotic run time of the body of the loop
  - Multiply them to get the overall asymptotic run time

## Warning: The following code fragments do NOT have the same runtime. Why?

```
diff = 0
for x in L:
    diff += abs(x - sum(L)/len(L))

diff = 0
mean = sum(L)/len(L)
for x in L:
    diff += abs(x-mean)
```

Be very careful about what steps are put inside the loop body. Try to move non-O(1) stops outside the loop body, when possible.

## What if there are nested loops?

- You can take different approaches:
  - Work from the innermost loop to the outermost
  - Work from the outermost loop to the innermost
- Nested loops can lead to nested sums

## What is the running time of mult\_table(n)?

```
def mult_table(n):
    table = [0]*n
    row = 0
    columns = list(range(n))
    while row < n:
        this_row = []
        for c in columns:
            this_row.append((row+1)*(c+1))
        table[row] = this_row
        row = row + 1
    return table
```

#### Useful summations

- $\sum_{i=1}^{n} 1 = O(n)$
- $\sum_{i=1}^{n} i = O(n^2)$
- $\sum_{i=1}^{n} n = O(n^2)$
- $\sum_{i=1}^{n} \sum_{j=1}^{n} 1 = O(n^2)$

## How do we determine runtime of recursive code?

```
def list_max(L):
  if len(L) == 1:
     return L[0]
  else:
     return
       max(L[0],
        list_max(
           L[1:]))
```

- Count steps for:
  - Determine len(L)
  - Compare to 1
  - Calculate L[0]
  - Calculate L[1:]
  - Call list\_maxrecursively on a list of length n-1
  - Determine max of two values
- T(n) = O(n) + T(n-1)

## More generally ...

- To help in analyzing recursive code, we will use basic recurrence relations.
- We will express the running time of a problem of size n in terms of
  - Running time of the code other than recursion
  - Running time of recursive call(s)
- For example:

$$-T(n) = O(n) + T(n-1)$$

## Helpful recurrence relations

- Once we have such a recurrence relation, use the following rules to determine the overall running time.
- $T(n) = O(1) + T(n-1) \rightarrow O(n)$
- $T(n) = O(n) + T(n-1) \rightarrow O(n^2)$
- $T(n) = O(1) + T(n/2) \rightarrow O(\log n)$
- $T(n) = O(n) + 2T(n/2) \rightarrow O(n \log n)$ -  $T(n) = O(n) + T(n/2) \rightarrow O(n)$
- $T(n) = O(1) + T(n-1) + T(n-2) \rightarrow O(2^n)$ 
  - $-T(n) = O(1) + 2T(n-1) \rightarrow O(2^n)$
  - $-T(n) = O(n) + T(n-1) + T(n-2) \rightarrow O(2^n)$
  - $-T(n) = O(n) + 2T(n-1) \rightarrow O(2^n)$

## Here are two ways to find maximum in a list. Which is more efficient?

```
def list_max1(x):
    if len(x) == 1:
        return x[0]
    elif x[0] > list_max1(x[1:]):
        return x[0]
    else:
        return list_max1(x[1:])
def remember_max(m, y):
    if len(y) == 0:
        return m
    elif m > y[0]:
        return remember_max(m, y[1:])
    else:
        return remember_max(y[0], y[1:])
def list max2(x):
    return remember max(x[0], x[1:])
```

## Analysing abstract list functions

- map(f,L), filter(f,L) are at least O(n)
- Actual running time depends on running time of £
- Hint: Analyse the program as if it were a loop instead of map or filter

### Determine the running times

```
def duplicate3(L):
    return list(map(lambda x:x, L))
def first_chars(words):
    return list(map(lambda t: t[0],
                    filter(lambda s:len(s)>0,
                           words)))
def list_of_lists(n):
    return list(map(lambda x:
                       list(range(n)),
                     range(n)))
```

#### Overall comments

- We've provided just a basic introduction to runtime analysis
  - Especially for recursive code
  - We have made some simplifications
- The topic is very important, though, and even an introduction can help you design better programs.
- Like this topic?
  - CS234 (non-majors)
  - CS240 (majors)

## **Summary of Common Runtimes**

more quickly grow **Functions** 

	Common Name
O(1)	Constant
O(log n)	Logarithmic
O(n)	Linear
O(n log n)	Log Linear
O(n <sup>2</sup> )	Quadratic
O(2 <sup>n</sup> )	Exponential

Algorithms more slowly

#### Goals of Module 07

- Understand how to analyze Python code to determine its running time, including
  - Recursion
  - Iteration
  - Abstract list functions
- Understand basic run time categories
